

# Nervous System

# Why do animals need a nervous system?

- What characteristics do animals need in a nervous system?
  - ◆ fast
  - ◆ accurate
  - ◆ reset quickly

Poor bunny!

# Nervous system cells

## ■ Neuron

### ◆ a nerve cell

## ■ Structure fits function

- ◆ many entry points for signal
- ◆ one path out
- ◆ transmits signal

synaptic terminal

synapse

dendrite → cell body → axon

# Fun facts about neurons

- Most specialized cell in animals
- Longest cell
  - ◆ blue whale neuron
    - 10-30 meters
  - ◆ giraffe axon
    - 5 meters
  - ◆ human neuron
    - 1-2 meters

Nervous system allows for  
1 millisecond response time

# Transmission of a signal

- Think dominoes!

- ◆ start the signal

- knock down line of dominoes by tipping 1<sup>st</sup> one  
→ trigger the signal

- ◆ propagate the signal

- do dominoes move down the line?  
→ no, just a wave through them!

- ◆ re-set the system

- before you can do it again,  
have to set up dominoes again  
→ reset the axon

# Transmission of a nerve signal

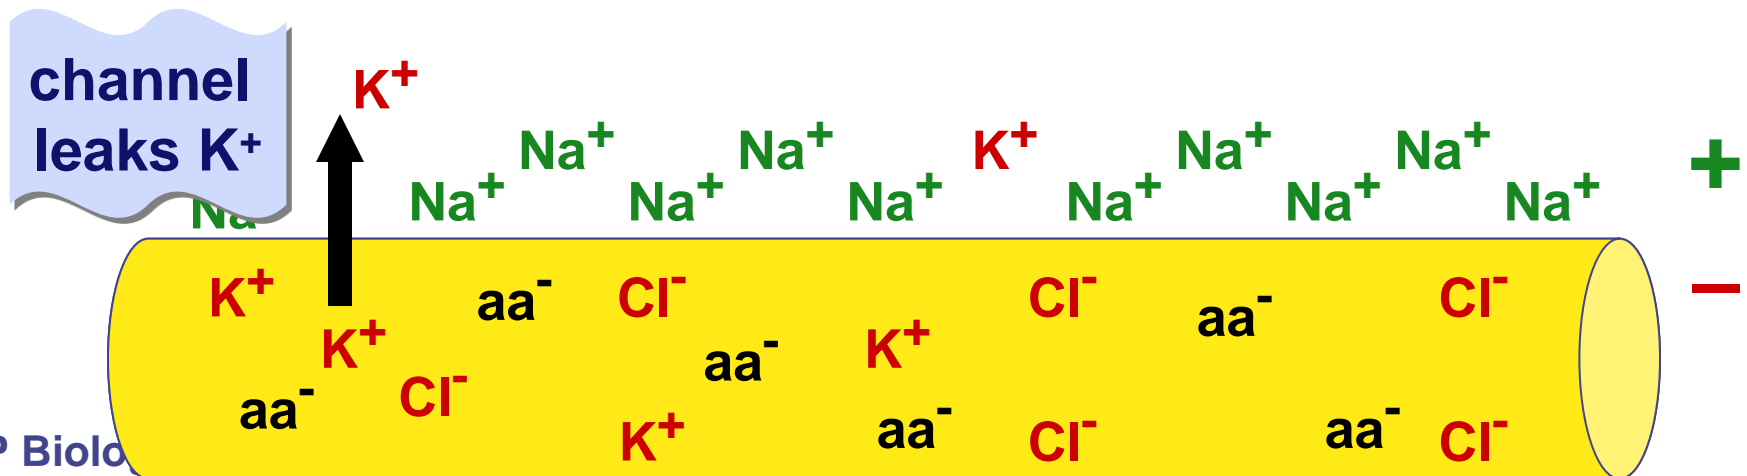

- Neuron has similar system
  - ◆ protein channels are set up
  - ◆ once first one is opened, the rest open in succession
    - all or nothing response
  - ◆ a “wave” action travels along neuron
  - ◆ have to re-set channels so neuron can react again

# Cells: surrounded by charged ions

- Cells live in a sea of charged ions
  - anions (negative)
    - more concentrated within the cell
    - $\text{Cl}^-$ , charged amino acids ( $\text{aa}^-$ )
  - cations (positive)
    - more concentrated in the extracellular fluid
    - $\text{Na}^+$

# Cells have voltage!

- Opposite charges on opposite sides of cell membrane
  - ◆ membrane is polarized
    - negative inside; positive outside
    - charge gradient
    - stored energy (like a battery)

# Measuring cell voltage

unstimulated neuron = resting potential of  $-70\text{ mV}$

# How does a nerve impulse travel?

- **Stimulus**: nerve is stimulated
  - ◆ reaches **threshold potential**
    - open **Na<sup>+</sup> channels** in cell membrane
    - Na<sup>+</sup> ions diffuse into cell
  - ◆ charges reverse at that point on neuron
    - positive inside; negative outside
    - cell becomes **depolarized**

The 1st  
domino  
goes  
down!

# How does a nerve impulse travel?

- **Wave**: nerve impulse travels down neuron

- ◆ change in charge opens next  $\text{Na}^+$  gates down the line

- **“voltage-gated” channels**

- ◆  $\text{Na}^+$  ions continue to diffuse into cell

- ◆ “wave” moves down neuron = **action potential**

The rest  
of the  
dominoes  
fall!

# How does a nerve impulse travel?

- **Re-set**: 2nd wave travels down neuron
  - ◆ **K<sup>+</sup> channels** open
    - K<sup>+</sup> channels open up more slowly than Na<sup>+</sup> channels
  - ◆ K<sup>+</sup> ions diffuse out of cell
  - ◆ charges reverse back at that point
    - negative inside; positive outside

Set  
dominoes  
back up  
quickly!

# How does a nerve impulse travel?

- Combined waves travel down neuron
  - ◆ wave of opening ion channels moves down neuron
  - ◆ signal moves in one direction → → → → →
    - flow of  $K^+$  out of cell stops activation of  $Na^+$  channels in wrong direction

Ready  
for  
next time!

# How does a nerve impulse travel?

- Action potential propagates
  - ◆ wave = nerve impulse, or action potential
  - ◆ brain → finger tips in milliseconds!

In the  
blink of  
an eye!

# Voltage-gated channels

- Ion channels open & close in response to changes in charge across membrane
  - ◆  $\text{Na}^+$  channels open quickly in response to depolarization & close slowly
  - ◆  $\text{K}^+$  channels open slowly in response to depolarization & close slowly

Structure  
& function!

# How does the nerve re-set itself?

- After firing a neuron has to re-set itself
  - ◆  $\text{Na}^+$  needs to move back out
  - ◆  $\text{K}^+$  needs to move back in
  - ◆ both are moving against concentration gradients
    - need a pump!!

A lot of work to do here!

# How does the nerve re-set itself?

## ■ Sodium-Potassium pump

- ◆ active transport protein in membrane
  - requires ATP
- ◆ 3  $\text{Na}^+$  pumped out
- ◆ 2  $\text{K}^+$  pumped in
- ◆ re-sets charge across membrane

# Neuron is ready to fire again

resting potential

# Action potential graph

1. Resting potential
2. Stimulus reaches threshold potential
3. Depolarization  
Na<sup>+</sup> channels open;  
K<sup>+</sup> channels closed
4. Na<sup>+</sup> channels close;  
K<sup>+</sup> channels open
5. Repolarization  
reset charge gradient
6. Undershoot  
K<sup>+</sup> channels close slowly

# Myelin sheath

- Axon coated with Schwann cells

- ◆ insulates axon
- ◆ speeds signal
  - signal hops from node to node
  - saltatory conduction
- ◆ 150 m/sec vs. 5 m/sec  
(330 mph vs. 11 mph)

signal  
direction

myelin sheath

# What happens at the end of the axon?

Impulse has to jump the **synapse**!

- ◆ junction between neurons
- ◆ has to jump quickly from one cell to next

Synapse

How does the wave jump the gap?

# Chemical synapse

## ■ Events at synapse

- ◆ action potential depolarizes membrane
- ◆ opens  $\text{Ca}^{++}$  channels
- ◆ neurotransmitter vesicles fuse with membrane
- ◆ release neurotransmitter to synapse → diffusion
- ◆ neurotransmitter binds with protein receptor
  - ion-gated channels open
- ◆ neurotransmitter degraded or reabsorbed

We switched...  
from an electrical signal  
to a chemical signal

# Nerve impulse in next neuron

## ■ Post-synaptic neuron

### ◆ triggers nerve impulse in next nerve cell

- chemical signal opens **ion-gated** channels

- $\text{Na}^+$  diffuses into cell

- $\text{K}^+$  diffuses out of cell

- ◆ switch back to voltage-gated channel

Here we go again!

# Neurotransmitters

- **Acetylcholine**
  - ◆ transmit signal to skeletal muscle
- **Epinephrine (adrenaline) & norepinephrine**
  - ◆ fight-or-flight response
- **Dopamine**
  - ◆ widespread in brain
  - ◆ affects sleep, mood, attention & learning
  - ◆ lack of dopamine in brain associated with Parkinson's disease
  - ◆ excessive dopamine linked to schizophrenia
- **Serotonin**
  - ◆ widespread in brain
  - ◆ affects sleep, mood, attention & learning

# Neurotransmitters

- **Weak point of nervous system**
  - ◆ any substance that affects neurotransmitters or mimics them affects nerve function
    - gases: nitrous oxide, carbon monoxide
    - mood altering drugs:
      - ◆ stimulants
        - amphetamines, caffeine, nicotine
      - ◆ depressants
        - quaaludes, barbiturates
    - hallucinogenic drugs: LSD, peyote
    - SSRIs: Prozac, Zoloft, Paxil
    - poisons

# Acetylcholinesterase

- Enzyme which breaks down acetylcholine neurotransmitter

- ◆ acetylcholinesterase inhibitors = neurotoxins
  - snake venom, sarin, insecticides

active site  
in red

acetylcholinesterase

neurotoxin  
in green

snake toxin blocking  
acetylcholinesterase active site

# Questions to ponder...

- Why are axons so long?
- Why have synapses at all?
- How do “mind altering drugs” work?
  - ◆ caffeine, alcohol, nicotine, marijuana...
- Do plants have a nervous system?
  - ◆ Do they need one?

**Ponder this...  
Any Questions??**
